1.1	Exercise 1 . . . . .	7
1.2	Exercise 2 . . . . .	7
1.3	Exercise 3 . . . . .	8

## 0.1 Big *O* Notation

Big *O* notation is used to describe the performance or complexity of an algorithm. It specifically describes the **worst-case** scenario, and can be used to describe the execution time required or the space used by an algorithm.

## 0.2 Functions

- Functions are **reusable** blocks of code that perform a specific task
- They can take input parameters and return output values
- Functions are essential in modular programming, as they help organize code and make it more readable

### 0.3 Defining a Function

- To define a function in Python, use the keyword `def` followed by the function name and input parameters in parentheses
- The function body is **indented** below the header line
- Use the keyword `return` to specify the output value(s) of the function

```
1 def add_numbers(x, y):
2     result = x + y
3     return result
4
5 type(add_numbers)
```

function

### 0.4 Calling a Function

To call a function, use its name followed by input values in parentheses. The function returns the output value(s), which can be stored in a variable or used directly.

```
1 sum = add_numbers(2, 3)
2 print(sum)
```

5

### 0.5 Default Parameter Values

- Functions can have default values for input parameters, which are used when no value is provided
- Default values are specified in the function header

```
1 def greet(name, greeting = "Hello"):
2     print(greeting + ", " + name)
3
4 greet("Alice")
```

Hello, Alice

```
1 greet("Bob", "Hi")
```

Hi, Bob

## 0.6 Variable-Length Arguments

- Variable-length arguments allow a function to accept any number of input arguments
- They are useful when the number of input arguments is unknown or can vary

```
1 def add_numbers(*args):
2     result = 0
3     for num in args:
4         result += num
5     return result
6
7 add_numbers
```

```
<function __main__.add_numbers(*args)>
```

```
1 add_numbers(1, 2)
```

3

```
1 add_numbers(1, 2, 3)
```

6

## 0.7 Function Annotation

```
1 def add_numbers(*args):
2
3     """
4     Computes the sum of n numbers
5
```

```

6     Parameters:
7     args: A tuple of numbers
8
9     Returns:
10    int: The sum
11    """
12
13    result = 0
14    for num in args:
15        result += num
16    return result
17
18 help(add_numbers)

```

Help on function add\_numbers in module \_\_main\_\_:

```

add_numbers(*args)
    Computes the sum of n numbers

    Parameters:
    args: A tuple of numbers

    Returns:
    int: The sum

```

## 0.8 Lambda Functions

- Lambda functions are **anonymous** functions that can be defined inline and used immediately
- They are useful for *simple* tasks that don't require a named function
- Lambda functions can only have **one** expression

```

1 double = lambda x: x * 2
2 print(double(3))

```

## 0.9 Recursion

- Recursion is a technique where a function calls itself
- It is useful for solving problems that can be broken down into smaller subproblems

```
1 def factorial(n):  
2     if n == 0:  
3         return 1  
4     else:  
5         return n * factorial(n-1)  
6  
7 print(factorial(5))
```

120

## 0.10 Global vs Local Variables

- Global variables are defined outside of any function and can be accessed from anywhere in the program
- Local variables are defined inside a function and can only be accessed within that function

```
1 global_var = 10  
2  
3 def my_func():  
4     local_var = 20  
5     print(global_var)  
6     print(local_var)  
7  
8 my_func()
```

10

20

```
1 print(global_var)
```

10

```
1 # print(local_var)
```

## 1 Exercises

### 1.1 Exercise 1

Python function that takes a list of numbers and returns their product

```
1 multiply_numbers([2, 3, 4])
```

24

```
1 def multiply_numbers(numbers):
2     product = 1
3     for num in numbers:
4         product *= num
5     return product
```

### 1.2 Exercise 2

Write a Python function to find the maximum and minimum numbers in a list

```
1 find_min_max ([2, 3, 4])
```

(2, 4)

```
1 def find_min_max(numbers):
2     min_num = numbers[0] # Set the min to the first number in the list
3     max_num = numbers[0] # Set the max to the first number in the list
4     for num in numbers:
5         if num > max_num:
6             max_num = num
7         elif num < min_num:
8             min_num = num
9     return (min_num, max_num)
```

```
10
11 find_min_max ([2, 3, 4])
```

(2, 4)

### 1.3 Exercise 3

Write a Python function that takes a list of strings and returns the longest string.

```
1 find_longest_string(["Vicky", "Cristina", "Barcelona"])

'Barcelona'

1 def find_longest_string(strings):
2     # Set the longest string to first string in the list
3     longest_string = strings[0]
4     for string in strings:
5         # Compare the length of the current string to the longest string so
6         ↪ far
7         if len(string) > len(longest_string):
8             longest_string = string
9     return longest_string
10 find_longest_string(["Vicky", "Cristina", "Barcelona"])

'Barcelona'
```
